## Abstracted Bag Container

```
class Bag
{
public:
    Bag(int bagCapacity = 10); // Constructor
    ~Bag(); // Destructor

    int Size() const; // Return the number of elements
    bool IsEmpty() const; // Check if bag is empty
    int Element() const; // Return an element in the bag

    void Push(const int); // Insert an integer into the bag
    void Pop(); // Delete an integer from the bag

private:
    int *array; // Integer array that stores the data
    int capacity; // Capacity of array
    int top; // Position of top element
};
```

# Bag Implementation

```
Bag::Bag( int bagCapacity):capacity( bagCapacity ) {
    if(capacity < 1) throw "Capacity must be > 0";
    array = new int [ capacity ];
    top = -1;}

Bag::~Bag(){ delete [] array; }

inline int Bag::Size() const { return top + 1; }

inline bool Bag::IsEmpty() const { return Size() == 0; }

inline int Bag::Element() const {
    if(IsEmpty()) throw "Bag is empty";
    return array [0]; // Always return the first element
}

void Bag::Push(const int x) {
    if(capacity == top+1) ChangeSize1D(array, capacity, 2* capacity);
    capacity *= 2;
    array[++top]=x;}

void Bag::Pop( ) {
    if(IsEmpty()) throw "Bag is empty, cannot delete";
    int deletePos = top / 2; // Always delete the middle element
    copy (array+deletePos+1, array+top+1, array+deletePos);
    top--;
}
```

3

## Abstracted Bag Container

```
template<class T>
class Bag
{
public:
    Bag(int bagCapacity = 10); // Constructor
    ~Bag(); // Destructor

    int Size() const; // Return the number of elements
    bool IsEmpty() const; // Check if bag is empty
    T& Element() const; // Return an element in the bag

    void Push(const T&); // Insert an element into the bag
    void Pop(); // Delete an element from the bag

private:
    T *array; // Data array
    int capacity; // Capacity of array
    int top; // Position of top element
};
```

4

# Template Bag Implementation

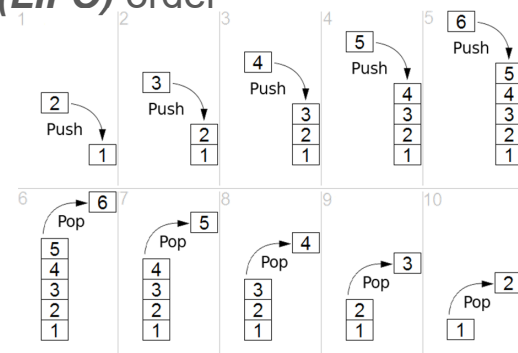

```
template<class T>
Bag<T>::Bag( int bagCapacity):capacity( bagCapacity ) {
    if(capacity < 1) throw "Capacity must be > 0";
    array = new T [ capacity ];
    top = -1;
}

template<class T>
void Bag<T>::Push(const T& x) {
    if(capacity == top+1) ChangeSize1D(array, capacity, 2* capacity);
    capacity *= 2;
    array[++top]=x;
}

template<class T>
void Bag<T>::Pop() {
    if(IsEmpty()) throw "Bag is empty, cannot delete";
    int deletePos = top / 2; // Always delete the middle emelent
    copy (array+deletePos+1, array+top+1, array+deletePos);
    array[top--].~T();
}
```

## Stack

- A stack is an ordered list
  - in which
    - insertions (or called additions or **pushes**)
    - deletions (or called removals or **pops**)
    - Both made at one end called the top
  - Operate in ***Last-In-First-Out (LIFO)*** order

# Stack: ADT

```
template < class T >
class Stack // A finite ordered list
{
public:
    // Constructor
    Stack (int stackCapacity = 10);

    // Check if the stack is empty
    bool IsEmpty ( ) const;

    // Return the top element
    T& Top ( ) const;

    // Insert a new element at top
    void Push (const T& item);

    // Delete one element from top
    void Pop ( );
private:
    T* stack;
    int top;    // init. value = -1
    int capacity;
};
```

Yi-Shin Chen -- Data Structures

7

## Stack Operations: Push & Pop

```
template < class T >
void Stack < T >::Push (const T& x)
{
    // Add x to stack
    if(top == capacity - 1)
    {
        ChangeSize1D(stack, capacity, 2*capacity);
        capacity *= 2;
    }
    stack [ ++top ] = x;
}
```

```
template < class T >
void Stack < T >::Pop ( )
{
    // Delete top element from stack
    if(IsEmpty()) throw "Stack is empty. Cannot delete.";
    stack [ top-- ].~T(); // Delete the element
}
```

# Queue

- A queue is an ordered list
  - in which
    - insertions (or called additions or pushes)
    - deletions (or called removals or pops)
    - Made at **different ends**
  - New elements are inserted at **rear** end
  - Old elements are deleted at **front** end
  - Operate in ***First-In-First-Out (FIFO)*** order

## Queue Insertion

- Insert a new element into queue
  - f: front position
  - r: rear position

# Queue Deletion

## ■ Delete an old element from queue

- f: front position
- r: rear position

# Problems

## ■ What happen if $\text{rear} == \text{capacity} - 1$ ?

## ■ Approach 1: Add more space

## ■ Approach 2: Shift left

Codes are complicated...

# Circular Queue

Initial

Insertion

Deletion

$\text{rear} = (\text{rear} + 1) \% \text{capacity};$

## Circular Queue: Empty

■  $\text{rear} == \text{front} ?$

Queue is empty

Queue is full

Allocate addition space before the queue is full

# Circular Queue

Initial

Insertion

Deletion

$\text{rear} = (\text{rear} + 1) \% \text{capacity};$

## Queue: ADT

```
template < class T >
class Queue // A finite ordered list
{
public:
    // Constructor
    Queue (int queueCapacity = 10);

    // Check if the stack is empty
    bool IsEmpty ( ) const;

    // Return the front element
    T& Front ( ) const;

    // Return the rear element
    T& Rear ( ) const;

    // Insert a new element at rear
    void Push (const T& item);

    // Delete one element from front
    void Pop ( );

private:
    T* queue;
    int front, rear; // init. value = -1 = capacity - 1
    int capacity;
};
```

## Queue Operations: Front & Rear

```
template < class T >
void Queue < T >::IsEmpty() const { return front==rear; }

template < class T >
T& Queue < T >::Front() const {
    if(IsEmpty()) throw "Queue is empty!";
    return queue[(front+1)%capacity];
}

template < class T >
T& Queue < T >::Rear() const {
    if(IsEmpty()) throw "Queue is empty!";
    return queue[rear];
}
```

## Queue Operations: Push & Pop

```
template < class T >
void Queue< T >::Push (const T& x)
{    // Add x at rear of queue
    if((rear+1)%capacity == front)
    {
        // queue is going to full, double the capacity!
    }
    rear = (rear+1)%capacity;
    queue [rear] = x;
}
```

```
template < class T >
void Queue < T >::Pop ( )
{    // Delete front element from queue
    if(IsEmpty()) throw "Queue is empty. Cannot delete.";
    front = (front+1)%capacity;
    queue[front].~T(); // Delete the element
}
```

# Subtype

## ■ Inheritance is used to express subtype relationships

- A Data object of Type B IS-A data object of Type A
- Type B is more specialized than Type A
- E.g., Chair IS-A Furniture

## ■ Bag is a data structure, where

- Elements can be inserted and deleted

## ■ Stack is a data structure, where

- Elements can be inserted and deleted

## ■ Stack is more specialized

- Stack IS-A Bag

# Generic Bag ADT

```
Class Bag
{
public:
    Bag(int bagCapacity=10);
    virtual ~Bag();
    virtual int Size() const;
    virtual bool IsEmpty() const;
    virtual int Element() const;
    virtual void Push(const int);
    virtual void Pop();
protected:
    int *array;
    int capacity;
    int top;
};
```

Implement operations not  
exist in the Bag class

```
class Stack : public Bag
{
public:
    Stack(int stackCapacity=10);
    virtual ~Stack();
    int Top() const;
    virtual void Pop();
};
```

## Expression

$$X = A/B - C + D * E - A * C$$

- Operators

- +, -, \*, /, ..., etc

- Operands

- A, B, C, D, E, F

- Execution order might affect the final result

## Expression Evaluation

- For  $X = A/B - C + D * E - A * C$

- If  $A = 4, B = C = 2, D = E = 3$

- $X = ((4/2) - 2) + (3 * 3) + (4 * 2) = 1$

- For  $X = (A / (B - C + D)) * (E - A) * C$

- If  $A = 4, B = C = 2, D = E = 3$

- $X = (4 / (2 - 2 + 3)) * (3 - 4) * 2 = -2.66666666$

# Evaluation Rules

- Operators have priority
- Operator with higher priority is evaluated first
- Operators of equal priority are evaluated from left to right
- Unary operators are evaluated from right to left

## Priority of Operators in CPP

Priority	Operators
1	Minus, !
2	*, /, %
3	+, -
4	<, <=, >=, >
5	=, !=
6	&&
7	

# Infix and Postfix Notation

## ■ Infix notation

- Operator comes in-between the operands
- E.g.,  $A+B*C$
- Hard to evaluate using codes...

## ■ Postfix notation

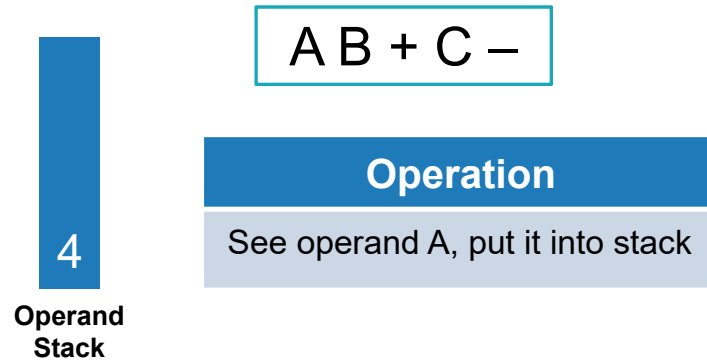

- Each operator appears after its operands
- E.g.,  $ABC^{*+}$

# Advantages of Postfix Notation

- You don't need parentheses
- Priority of operators is no longer relevant!
- Expression can be efficiently evaluated by
  - Making a left to right scan
  - **Stacking** operands
  - Evaluating operators
  - Push the result into stack

## Example 1

- Infix :  $A+B - C \Rightarrow$  Postfix :  $A B + C -$
- Suppose  $A = 4, B = 3, C = 2$

## Evaluation Pseudo Codes

```
void Eval(Expression e)
{
    // Assume the last token of e is '#'
    // A function NextToken is used to get next token in e
    Stack<Token> stack; // initialize stack
    for (Token x = NextToken(e); x != '#'; x = NextToken(e)) {
        if(x is an operand) stack.Push(x);
        else{
            // Remove the correct number of operands from stack
            // Perform the evaluation
            // Push the result back to stack
            // ***Try to fill up the codes by your own***
        }
    }
};
```

## Infix to Postfix

- Fully parenthesize algorithm:
  - Fully parenthesize the expression
  - Move all operators so they replace the corresponding right parentheses
  - Delete all parentheses

$((((A / B) - C) + (D * E)) - (A * C))$

## Infix to Postfix

- Smarter algorithm
  - Scan the expression only once
  - Utilize [stack](#)
- The order of operands does not change
- Output every visiting operand directly
- Use stack to store visited operators
  - Pop them out at the right moment
    - The **priority** of operator on top of stack is *higher or equal to* that of the incoming operator
    - left-to-right associativity

## Example 1

■ Infix :  $A + B * C$

## Example 2

■ Infix :  $A * ( B + C ) * D$

## Notes

### ■ Expression with ( )

- '(' has the highest priority, always push to stack.
- Once pushed, '(' get lowest priority.
- Pop the operators until you see the matched ')'

## Self-Study Topics

### ■ Prefix representation

infix	prefix
$A * B / C$	$/*ABC$
$A / B - C + D * E - A * C$	$-+ - / ABC * DE * AC$
$A * (B + C) / D - G$	$- / * A + BCDG$
